Here is a different case which, many think, the Probability Splitting Rule says just the right thing about.

The poll

I put an argument on the screen, and conduct a poll, asking you to say whether the argument is valid or invalid. You confidently answer "Valid." When the poll results show up, you find to your surprise that you are the only student who answered this way.

What should you say in this case? Why?

Why? We can think of this as a case in which you have many simultaneous disagreements. Supposing for simplicity that everyone initially has credence 1 in her answer, the Probability Splitting Rule would suggest that you should lower your credence in your initial answer to 0.5, then to 0.25, then to 0.125, then to .... a small number.

The probability splitting rule

If you assign P credence N, and come across someone who assigns P credence M, then you should assign as P's credence the average of N and M.

Does the probability splitting rule have any practical consequences?

Consider any religious, moral, or political view you have. There would seem to be plenty of people who have the same evidence as you, have thought about the issues as much as you, and are as smart as you, who have a view opposite to yours.

This suggests an argument with massive consequences for what you believe about these domains.

1. For virtually every moral, political, or religious view you have, you have at least roughly as many epistemic peers who disagree with you as you have epistemic peers who agree with you.
2. If you assign P credence N, and come across an epistemic peer who assigns P credence M, then you should change your credence in P to the average of N and M. (Probability-Splitting)

C. You should not have credence > 0.5 in virtually any moral, political, or religious claim.

The disagreement-agnosticism argument

Is it reasonable to deny premise (1)?

The poll
