Three views universe

But even if Aquinas' defense of (4) is unsuccessful, (4) might still be true. When you encounter an argument in which one of the premises is insufficiently well defended by the author, you should always ask: can we do better?

4. There are no infinite causal chains.

One attempt to do better begins with the thought that just because certain mathematical notions make sense, it does not automatically follow that every real world scenario involving those notions makes sense. For example, the idea of negative numbers makes sense. But would it make sense for me to say that I have -16 apples in my refrigerator? One might then try to make a parallel argument about infinity. Perhaps the idea of an infinite series of numbers makes sense, but the idea of an infinite causal chain does not.

One way to argue for this is to argue that, more generally, the idea of an infinite collection of things existing in space and time does not make sense.

Let's consider some curious features of infinite collections. Consider the collection of natural numbers

1, 2, 3, 4, 5, 6,

And compare this to the collection of even natural numbers

2, 4, 6, 8, ...

Which collection is bigger?

It is very natural to say: the collection of all of the natural numbers is bigger. After all, it contains everything in the collection of even numbers, and a bunch more things besides (namely, all of the odd numbers).

But this is incorrect: the two collections are of exactly the same size. To see this, note that we can match up the two collections, so that every member of one collection is paired with a member of the other collection. 1 is paired with 2, 2 with 4, 3 with 6, etc. We never run out of even numbers!

This example shows that you can have two infinite collections, A and B, which is such that A contains everything in B plus infinitely more things, and yet the same number of things are in the two collections.

If we think about real-world collections, this leads to some surprising results. Imagine that we had a library with infinitely many books. You walk in the front door to this library. To your left, there are as many books as there are even numbers. To your right, there are as many books as there are odd numbers. So there are infinitely many books in both directions.

You then compare two collections of books: the collection of all of the books in the library, and the collection of books just to your left. Which collection is bigger?

The correct answer would have to be: neither. The two collections are exactly the same size. (For just the same reason as the collection of natural numbers is the same size as the collection of evens.)

nothing like the Big Bang could genuinely be a first cause. Things like the Big

Bang have to have a cause; but things like God don't. But why?

This would appear to be a description of a world in which there is a first

some reason for rejecting the above hypothesis.

simple atheism. So it looks as though, if we are to believe (8), we must have

cause, but God does not exist. And it appears to be entirely consistent with

The Big Bang

The first event in the history of the universe was an explosion of an extremely dense collection of particles, with every particle moving apart from every other particle. This event had no cause - in particular, no being set it into motion - and, further, every subsequent event has been an effect of this event.
