

Enough about probability (for now). Let's turn now to some results from contemporary physics which will be important to the argument which follows.

A first question: what does the theory provide by physics include?

These 'dimensions' will be our focus.

One such constant is the cosmological constant, which measures the energy density of empty space.

Given assumptions such as these, we can look at what the standard model of physics tells us about how likely it is that, for example, the cosmological constant has a value which would permit the evolution of life.

$$Pr(e \mid \text{design}) = 0.5$$

$$Pr(\text{design}) = 0.5$$

$$Pr(\text{non-design} \mid e) = \frac{0.5 * \frac{1}{10^{120}}}{0.25} = \frac{2}{10^{120}}$$

fine-

objections

$$A = P(\text{design})$$

$$B = P(\text{life} \mid \text{design})$$

$$C = P(\text{life} \mid \text{non-design})$$

$$P(\text{design} \mid \text{life}) = \frac{A*B}{A*B + (1-A)*C}$$

We also know that $P(\text{non-design}) = 1 - P(\text{design})$. So there are really only three probabilities that we need to assign.

And we know from Bayes' theorem that

Let's have a look at how changing the probability assignments might change the probability that we should assign to the design hypothesis.

tuning of the
universe

A solid red circle serves as the background for the text.

Bayes'
theorem

“The standard model of physics presents a theory of the electromagnetic, weak, and strong forces, and a classification of all known elementary particles. The standard model specifies numerous physical laws, but that's not all it does. According to the standard model there are roughly two dozen dimensionless constants that characterize fundamental physical quantities.” (Hawthorne & Isaacs, “Fine-tuning fine-tuning”)

could have different values consistent with the laws of physics.

The cosmological constant is just a number which (as far as we know)

One thing that the standard model of physics gives us is a measure of how

(like the cosmological constant) would fall in a certain range.

likely it is, given the laws of the nature, that the fundamental constants

to see how life could have evolved.

hard to see how life could have evolved. If there were no planets, it is hard

life to have evolved. For example, if there were nothing but hydrogen, it is

We can make certain plausible assumptions about what it would take for

“Physicists have determined the (approximate) values of the fundamental constants by measurement.

(There's no way to derive the values of the fundamental constants from other aspects of the standard model. Any quantities that could be so derived wouldn't be fundamental.) Still, the underlying theory favored some sorts of parameter-values over others. ... Physicists made the startling discovery that -- given antecedently plausibly assumptions about the nature of the physical world -- the probability that a universe with general laws like ours would be habitable was staggeringly low.”

This is the claim that the cosmological constant having a life-

supporting value, given the laws of nature, is very low.

We should emphasize just how small we take the life-permitting parameter values to be according to the physically-respectable measures. “Small” here doesn’t mean “1 in 10,000” or “1 in 1,000,000”. It means the kind of fraction that one would resort to exponents to describe, as in “1 in 10 to the 120”. The kind of package that we have in mind tells us that only a fantastically small range is life permitting.
