God cannot
bring about the
good while also
eliminating the
evil

This is a serious problem for the believer in God. In general, as a being becomes more powerful, fewer evils become permissible for that being to allow. Imagine, for instance, that our dentist had new powers — like the power to do root canals while causing no pain. This more powerful dentist would **not** be permitted to allow pain while performing a root canal.

Because God is so powerful, it can be hard to see how any evils could be permissible for God to allow. It looks like any evil would have to be a pointless evil.

the 1990s, the number of people in the world who are undernourished has increased from 600 million to 800 million (FAO 2001).

There is a growing awareness of the need to improve the nutritional status of the world's population, and the World Health Organization (WHO) has set a target of halving the number of undernourished people in the world by the year 2015 (WHO 2000). This paper reports on a study that was designed to assess the impact of a community-based intervention on the nutritional status of children in a rural area of South India.

Background

Malnutrition is a global public health problem. In 1999, 15% of the world's population was undernourished, and 15% of children under the age of 5 years were malnourished (WHO 2000). In India, 17% of the population is undernourished, and 19% of children under the age of 5 years are malnourished (National Institute of Public Health and Nutrition 2000). The prevalence of malnutrition is higher in rural areas than in urban areas, and in South India than in North India.

There are a number of reasons why malnutrition is a problem in South India. One of the main reasons is the lack of access to food. Many people in South India live in rural areas, and they have to travel long distances to reach the markets. This makes it difficult for them to buy food, and it also makes it difficult for them to get the food that they need. Another reason is the lack of knowledge about nutrition. Many people in South India do not know what to eat, and they do not know how to cook food. This makes it difficult for them to get the nutrition that they need.

There are a number of ways to improve the nutritional status of the population in South India. One way is to improve access to food. This can be done by building roads and bridges, and by improving the transportation system. Another way is to improve knowledge about nutrition. This can be done by providing education and training to the population. A third way is to provide food and nutrition supplements to the population.

This paper reports on a study that was designed to assess the impact of a community-based intervention on the nutritional status of children in a rural area of South India. The intervention was designed to improve access to food, improve knowledge about nutrition, and provide food and nutrition supplements to the population. The study was conducted in a rural area of South India, and it involved 100 children under the age of 5 years.

The study was conducted in a rural area of South India, and it involved 100 children under the age of 5 years. The children were selected from a list of all children in the area, and they were divided into two groups. The first group was the control group, and the second group was the intervention group. The children in the control group did not receive any intervention, and the children in the intervention group received the community-based intervention.

The intervention was designed to improve access to food, improve knowledge about nutrition, and provide food and nutrition supplements to the population. The intervention was implemented by a community health worker, and it involved providing food and nutrition supplements to the children, and providing education and training to the parents. The intervention was implemented for 12 months, and the impact of the intervention was assessed at the end of the 12 months.

The impact of the intervention was assessed by measuring the nutritional status of the children. The nutritional status of the children was measured using the following indicators: weight-for-age, height-for-age, and weight-for-height. The results of the study showed that the intervention had a positive impact on the nutritional status of the children. The children in the intervention group had a higher weight-for-age, a higher height-for-age, and a higher weight-for-height than the children in the control group.
